GENOME ANNOUNCEMENT ===== *Enterovirus B (EV-B)* species belong to the human *Picornaviridae* family and are classified into several different types ([@B1]). Enterovirus B80 (EV-B80) was first reported in 1999 and was detected in patients with acute type B-poliovirus (B-poliovirus) infection ([@B2]). EV-B80 causes severe diseases, such as myocarditis, encephalitis, pneumonia, and central nervous system (CNS) diseases ([@B3]). EV-B80 is one of the major causes of acute flaccid paralysis in Japan ([@B4]). EV-B80 was first isolated in our laboratory from a patient with acute flaccid paralysis in Tokyo in 2005 ([@B5]). EV-B80 had been detected in CSF samples from two patients with acute flaccid paralysis with a similar clinical manifestation. One of these patients was a male patient with diphtheria from Osaka, Japan, and the other was a female patient with multiple sclerosis (MS) from Osaka, Japan ([@B5], [@B6]). Novel EV-B80 strain D4 was isolated from the CSF sample of a patient with acute flaccid paralysis in Japan in 2006. This strain was isolated in Madin-Darby canine kidney cells (MDCK cells) and was named EV-B80/D4. The EV-B80 strain D4 was detected in CSF samples from four patients with acute flaccid paralysis in Japan, and only these four strains were isolated from patients with the same clinical manifestations. The patient was a male patient of 22 years of age living in Osaka, Japan. EV-B80 strain D4 was also detected in the CSF sample of an adult healthy patient in Japan, who had not been exposed to polio vaccination, indicating that the patient was not immunocompromised and that EV-B80 was not actively spreading in Japan. The complete genome sequence of EV-B80 strain D4 was determined using a sequencing method as described previously ([@B7], [@B8]). Briefly, EV-B80 strain D4 genome was sequenced using a shotgun sequencing strategy in an Illumina HiSeq 2000 sequencer by using Illumina paired-end reads. The obtained reads were assembled using Velvet version 0.7.61 and Velvet

What's New In Photoshop 2020?

The present invention relates to aircraft rotor blades and, in particular, to a rotor blade having spliceable torque box parts and a method of building such rotor blades. Aircraft rotor blades, such as rotor blades for helicopters and other aircraft, are traditionally constructed with a spar to provide axial support, an inboard/outboard or torque box assembly to provide lateral support, and blade skin which is bonded or riveted to the spar and torque box assembly. The torque box assembly, also known as a clamshell, traditionally includes a pressure case, a suction case, and sealing members for providing a fluid seal between the cases. The torque box, in particular, provides strength and stiffness to the rotor blade and maintains structural integrity of the blade. Spliceable torque boxes are also used in the rotor blade fabrication process. It is desirable to fabricate the rotor blade from a combination of composite materials in order to reduce the weight of the rotor blade while providing high strength and fatigue life. Composite rotor blades are typically constructed by assembling individual composite layers, such as spars, boxlets and/or shell plates, with one or more resin layers between the individual layers. A rotor blade is typically constructed in this manner, layer by layer, using a lay-up process. When constructing a rotor blade, it is desirable to ensure that the various layers are aligned and properly positioned. In an aircraft rotor blade, the torque boxes are typically spliceably connected to form the torque box assembly. The clamshell will be formed from two or more segments. The splicing of these segments is performed, for example, by the force of friction or riveting to securely couple the segments together. However, the spliced connections between the torque boxes traditionally rely on friction or riveting. The friction is difficult to maintain at the splice as the torque boxes expand, particularly when the blade undergoes temperature cycling. The rivets or other fasteners are difficult to eliminate and/or prevent. As a result, the integrity of the clamshell and the internal torque boxes can be compromised. Accordingly, a rotor blade, having spliceable torque box parts and a method of building the same, is desired. It is also desired to provide a spliced connection having improved integrity. A method of splicing spliceable torque box parts for fabricating a rotor blade of a helicopter includes assembling a core formed from two or more segments. The segments are spliced together with an adhesive. The adhesive then cures, and the segments
